an investigation into the assignment of moral responsibilities and rights to intelligent and autonomous machines of our own making one of the enduring concerns of moral philosophy is deciding who or what is deserving of ethical consideration much recent attention has been

devoted to the animal question consideration of the moral status of nonhuman animals in this book david gunkel takes up the machine question whether and to what extent intelligent and autonomous machines of our own making can be considered to have legitimate moral responsibilities and any legitimate claim to moral consideration the machine question poses a fundamental challenge to moral thinking questioning the traditional philosophical conceptualization of technology as a tool or instrument to be used by human agents gunkel begins by addressing the question of machine moral agency whether a machine might be considered a legitimate moral agent that could be held responsible for decisions and actions he then approaches the machine question from the other side considering whether a machine might be a moral patient due legitimate moral consideration finally gunkel considers some recent innovations in moral philosophy and critical theory that complicate the machine question deconstructing the binary agent patient opposition itself technological advances may prompt us to wonder if the science fiction of computers and robots whose actions affect their human companions think of hal in 2001 a space odyssey could become science fact gunkel s argument promises to influence future considerations of ethics ourselves and the other entities who inhabit this world

an examination of more than sixty years of successes and failures in developing technologies that allow computers to understand human spoken language stanley kubrick s 1968 film 2001 a space odyssey famously featured hal a computer with the ability to hold lengthy conversations with his fellow space travelers more than forty years later we have advanced computer technology that kubrick never imagined but we do not have computers that talk and understand speech as hal did is it a failure of our technology that we have not gotten much further than an automated voice that tells us to say or press 1 or is there something fundamental in human language and speech that we do not yet understand deeply enough to be able to replicate in a

computer in the voice in the machine roberto pieraccini examines six decades of work in science and technology to develop computers that can interact with humans using speech and the industry that has arisen around the quest for these technologies he shows that although the computers today that understand speech may not have hal s capacity for conversation they have capabilities that make them usable in many applications today and are on a fast track of improvement and innovation pieraccini describes the evolution of speech recognition and speech understanding processes from waveform methods to artificial intelligence approaches to statistical learning and modeling of human speech based on a rigorous mathematical model specifically hidden markov models hmm he details the development of dialog systems the ability to produce speech and the process of bringing talking machines to the market finally he asks a question that only the future can answer will we end up with hal like computers or something completely unexpected

this book presents a new and exciting theory of the modern french novel by developing the notion of the narrative as a textual machine many turn of the century french novels thematically identified their means of narration through the various machines that they depicted the narrative devices that were particularly important in this self reflection included the temporal order of the plot the question of a narrative s beginning and end the hierarchy of narrative voices and the techniques of the point of view the question of mechanization became central on all these fronts has the novel become automated or machine like at the same time the machine metaphors in the novels of alfred jarry emile zola jules verne villiers de l isle adam raymond roussel combined the question of the narrative form with new ways to think about man s relationship with technology and the cultural environment the early modernist texts drew upon contradictory notions of technological promise and threat while they also depicted new forms of identity and

behavior related to or modeled after machines these texts highlighted cultural assumptions concerning technological innovations and critiqued mainly through parody and through various figures of man machine fusion the positivistic belief in progress such writers looked for evidence of advanced forms of consciousness arising out of encounters with new technology such as telephones trains bicycles telegraphy phonographs and electricity this volume will be of interest to anyone working in the field of modern french literary and cultural history it will especially appeal to anyone intrigued with the origins of the modernist novel the history of narrative forms and the question of how the experience of new technology may be portrayed in literary texts

Unveiling Earth's Sculptured Surface:

Understanding Landform Formation

The Earth's surface is a tapestry woven from a diverse array of landforms – towering mountains, sprawling plains, deep canyons, and meandering rivers. Understanding how these features are formed is crucial not only for appreciating the planet's beauty but also for comprehending its dynamic geological processes, predicting natural hazards, and managing resources effectively. This article delves into the fascinating world of landform formation, addressing common challenges and misconceptions along the way.

1. The Power of Tectonic Plates: Building Mountains and Shaping Continents

The Earth's lithosphere is broken into several massive plates that constantly move, albeit slowly. This plate tectonics theory is the cornerstone of understanding large-scale landform formation. Types of Plate Boundaries and their Landform Impacts: Convergent Boundaries: When plates collide, the denser plate subducts (slides beneath) the other. This process often creates: Mountain Ranges: The collision forces uplift the crust, forming immense mountain ranges like the Himalayas (formed by the Indian and Eurasian plates colliding). Volcanoes: Magma generated by the subducting plate rises to the surface, creating volcanic mountain chains along the convergent boundary, like the Andes Mountains. Ocean Trenches: The subduction zone creates deep ocean trenches, the deepest parts of the ocean floor, like the

Mariana Trench. Divergent Boundaries: Where plates move apart, magma rises to fill the gap, forming: Mid-Ocean Ridges: Underwater mountain ranges formed by the upwelling magma, creating new oceanic crust. The Mid-Atlantic Ridge is a prime example. Rift Valleys: On continents, divergent boundaries can create rift valleys, long, narrow depressions like the East African Rift Valley, potentially leading to continental breakup. Transform Boundaries: Plates slide past each other horizontally, causing: Faults and Earthquakes: The friction between plates builds up stress, which is released suddenly as earthquakes. The San Andreas Fault in California is a classic example. While not directly creating major landforms in the same way as convergent or divergent boundaries, transform boundaries significantly influence the landscape by fracturing and offsetting existing features. Challenges in understanding tectonic landform formation: One significant challenge is the immense timescale involved. Millions of years are required to form major landforms like mountain ranges, making direct observation impossible. Scientists rely on indirect evidence such as rock formations, fossil records, and seismic data to reconstruct the history of plate movements.

2. The Sculpting Hand of Erosion and Weathering: Shaping the Landscape

While tectonic forces build the Earth's grand structures, erosion and weathering continuously reshape them. Weathering: The breakdown of rocks in situ (in place) through physical and chemical processes. Physical Weathering: Processes like freeze-thaw cycles (water expanding as it freezes), abrasion by wind or water, and exfoliation (peeling of rock layers) break down rocks into smaller fragments. Chemical Weathering: Reactions between rocks and water, air, or

other chemicals dissolve or alter the rock's composition, weakening it. Examples include oxidation (rusting) and hydrolysis (reaction with water). Erosion: The transport of weathered material by agents like water, wind, ice, and gravity. Water Erosion: Rivers carve valleys, create canyons (like the Grand Canyon), and deposit sediments to form deltas and alluvial fans. Wind Erosion: Wind picks up and carries fine particles, sculpting landscapes through abrasion and deposition, creating features like sand dunes and desert pavements. Glacial Erosion: Glaciers carve U-shaped valleys, transport massive amounts of rock (forming moraines), and create features like cirques and fjords. Mass Wasting: Gravity-driven movement of rock and soil downslope, including landslides, rockfalls, and mudflows, significantly alters the landscape. Challenges in studying erosion and weathering: The rate of erosion and weathering varies significantly depending on factors like climate, rock type, and vegetation cover. Accurately modeling these processes and predicting their long-term effects is a complex challenge, particularly in the context of climate change.

3. Deposition: Building New Land

Erosion transports weathered material, which is eventually deposited in new locations, creating various landforms. Rivers deposit sediments to form floodplains, deltas, and alluvial fans. Glaciers leave behind moraines and drumlins. Wind deposits sand to form dunes and loess deposits. These depositional processes constantly reshape the Earth's surface, often burying older landforms.

Summary

Landform formation is a complex interplay of tectonic processes that build the Earth's major structures and erosional processes that constantly modify and reshape them. Understanding these interactions requires considering the immense timescales involved and the intricate relationships between plate tectonics, weathering, erosion, and deposition. By studying the geological record and employing advanced modeling techniques, scientists continue to refine our understanding of this dynamic and ever-evolving process.

FAQs

1. What is the difference between a plateau and a mesa? A plateau is a large, elevated area of relatively flat land, while a mesa is a smaller, isolated plateau with steep sides. 2. How are caves formed? Caves are typically formed by the dissolution of soluble rocks, such as limestone, by slightly acidic groundwater. 3. Can human activities impact landform formation? Yes, human activities such as deforestation, mining, and dam construction can significantly alter erosion rates and landform evolution. 4. What is isostasy and how does it affect landforms? Isostasy is the state of gravitational equilibrium between Earth's crust and mantle. Changes in the crust's mass (e.g., due to glacial melting or mountain building) cause isostatic adjustment, leading to land uplift or subsidence. 5. How do we date landforms? Various techniques are used, including radiometric dating of rocks, analysis of fossil evidence, and studying the layers of sediment deposition (stratigraphy). These methods allow scientists to reconstruct the timeline of landform evolution.
